Research Motivation

A new algorithm for text tree edit distance based on Zhang-Shasha's algorithm and BERT-like model embedding similarity.

The algorithm's novelty is in its similarity measure based on BERT-like model embeddings.

The proposed algorithm is presented as a more informative metric of similarity between text trees.

Zhang-Shasha's algorithm is used to compute tree edit distance with new edit costs.

Embedding distance is used as a measure of semantic similarity.

The language model allows to capture semantic meaning of sentences and model their similarity.

The current ways of comparing text trees overlook their tree structure or the meaning of their labels.

This new method can be used, for example, to compare mind maps or hierarchical summaries.

Semantic similarity is used as the update cost in the algorithm.

The costs of insertion and removal of nodes are defined as the similarity of the node and an empty sentence.

An example of a text tree — a hierarchical summary of this study in the form of a *mind map*

Problem: How to compare hierarchical summaries, considering both their structure and semantics?

Hierarchical Summarization Problem Statement

Let \mathcal{S} be the *set of texts* over a given vocabulary.

Text tree — a tree $T = (V, E)$, where $E \subset V^2$ and for each $v \in V$ a text $s(v) \in \mathcal{S}$ is defined.

\mathcal{T} — the considered *set of text trees*.

Task: Find a mapping $f : D \mapsto T$ that constructs a hierarchical summary $T \in \mathcal{T}$ from a document D , minimally different from a reference summary T^* of D constructed by an expert:

$$\rho(f(D), T^*) \longrightarrow \min_f .$$

Question: How do we choose the metric $\rho : \mathcal{T}^2 \rightarrow \mathbb{R}_+$?

Proposed Metric — TTED

TTED (*text tree edit distance*) — tree edit distance¹, where the cost of edit operations is:

- a) replacement of vertex v with v' : $r(s(v), s(v'))$;
- b) addition/removal of vertex v : $r(s(v), \lambda)$;

where λ — empty string.

Semantic distance r can be measured as the distance between *embeddings* (vector representations) of texts, obtained using a language model $\text{LM} : \mathcal{S} \rightarrow \mathbb{R}^n$:

$$\forall s, s' \in \mathcal{S} \quad r(s, s') = \rho_n(\text{LM}(s), \text{LM}(s')),$$

where ρ_n — a metric in \mathbb{R}^n .

Baseline Text Tree Comparison Method

In the study of *Zhang et al., 2024*² the similarity of text trees $T = (V, E)$ and $T' = (V', E')$ is defined as

$$\text{Sim}(T, T') = \max_{P \subset E \times E'} \sum_{(e, e') \in P} \sum_{i=0,1} \text{ROUGE}(e_i, e'_i).$$

where P — a one-to-one mapping of edges of T to edges of T' (the optimal one is found by a greedy algorithm), $\text{ROUGE}(v, v')$ — the averaged ROUGE-1, ROUGE-2, and ROUGE-L similarity score of $s(v)$ and $s(v')$.

For consistency, the distance measure used is

$$\rho(T, T') = \sqrt{\text{Sim}(T, T) + \text{Sim}(T', T') - \text{Sim}(T, T') - \text{Sim}(T', T)}.$$

Aspects of Text Tree Difference

Let for $T \in \mathcal{T}$ the following sets of trees be defined:

1. $P(T)$ — trees differing from T only in paraphrasing;
2. $S(T)$ — trees differing from T only in structure;
3. $M(T)$ — trees differing from T only in semantics (in meaning/content).

Idea: for an adequate metric ρ on \mathcal{T} it should hold that

$$\langle \rho(T, T') \rangle_{T' \in P(T)} \ll \langle \rho(T, T'') \rangle_{T'' \in S(T)},$$

$$\langle \rho(T, T') \rangle_{T' \in P(T)} \ll \langle \rho(T, T''') \rangle_{T''' \in M(T)}.$$

Metric Quality Criteria

Consider a sample $\mathcal{D} = \{T, T'_1, \dots, T'_p, T''_1, \dots, T''_s, T'''_1, \dots, T'''_m\}$, where $T \in \mathcal{T}$, $T'_i \in P(T)$, $T''_j \in S(T)$, $T'''_k \in M(T)$.

Quality coefficients of metric ρ on sample \mathcal{D} :

$$R_S^{\mathcal{D}}(\rho) = \frac{1}{sp} \sum_{i=1}^p \sum_{j=1}^s \frac{\rho(T, T'_i)}{\rho(T, T''_j)}, \quad R_M^{\mathcal{D}}(\rho) = \frac{1}{mp} \sum_{i=1}^p \sum_{k=1}^m \frac{\rho(T, T'_i)}{\rho(T, T'''_k)}.$$

$R_S^{\mathcal{D}}(\rho)$ — sensitivity of metric ρ to **paraphrasing** relative to **structure**;

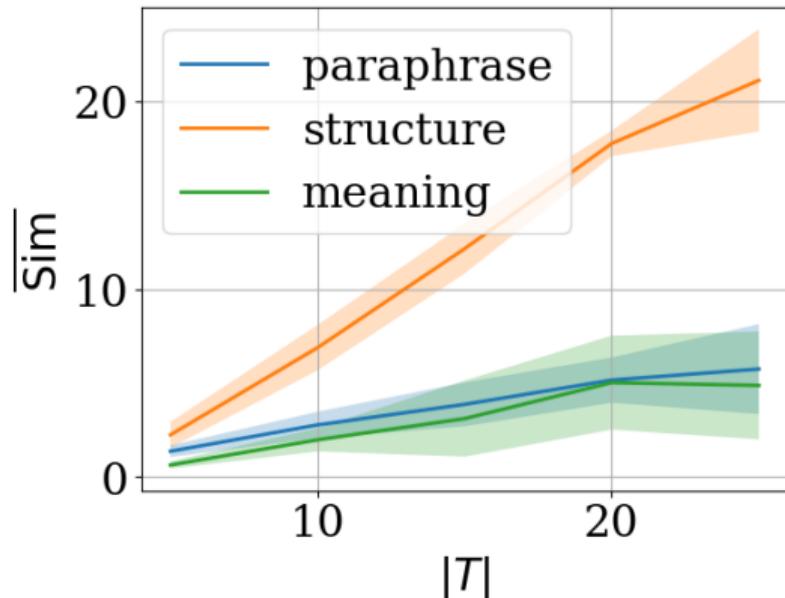

$R_M^{\mathcal{D}}(\rho)$ — sensitivity to **paraphrasing** relative to **semantics**.

Optimization problem:

$$R_S^{\mathcal{D}}(\rho) \rightarrow \min_{\rho}, \quad R_M^{\mathcal{D}}(\rho) \rightarrow \min_{\rho}.$$

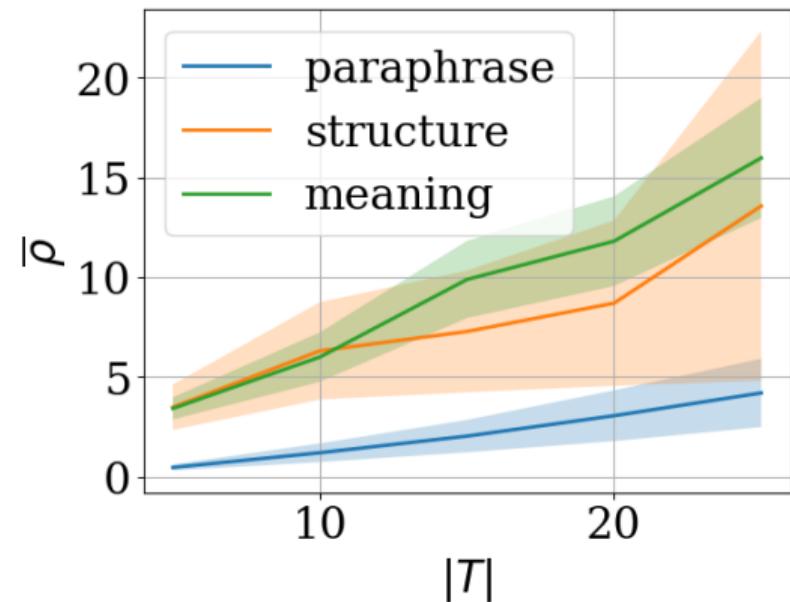

Method Testing — Results

a) Average values of the baseline similarity coefficient

$\text{Sim}(\cdot, \cdot)$ reflects differences in semantics and paraphrasing similarly, noticeably less so for structure.

b) Average values of the TTED distance

TTED reflects differences in paraphrasing noticeably less than in structure and semantics, reflected similarly.

Metric Testing — Results

Results of tests for the baseline distance measure and TTED with different encoder models for text embedding generation on synthetic data

Method	$R_S^D(\rho)$	$R_M^D(\rho)$
Baseline	2.05 ± 0.79	0.96 ± 0.10
TTED with DistilRoBERTa	0.58 ± 0.22	0.53 ± 0.11
TTED with SPECTER	0.69 ± 0.35	0.46 ± 0.14
TTED with MPNet	0.44 ± 0.12	0.48 ± 0.11
TTED with fine-tuned MPNet	0.61 ± 0.78	0.45 ± 0.12

Significant differences compared to insignificant ones are reflected better by TTED than by the baseline method.

Testing TTED Modifications

Dependence of quality coefficients on the **metric for comparing embeddings** in TTED

$r(x, y)$	$\bar{\rho}_1, T = 10$	$\bar{\rho}_3, T = 10$	$R_M^D(\rho)$
$\sqrt{1 - S_C(x, y)}$	3.89 ± 0.71	8.41 ± 0.80	0.48 ± 0.11
$\ x - y\ _2$	5.50 ± 1.00	11.89 ± 1.14	0.48 ± 0.11
$\ x - y\ _1$	119.70 ± 21.60	259.05 ± 25.12	0.48 ± 0.11

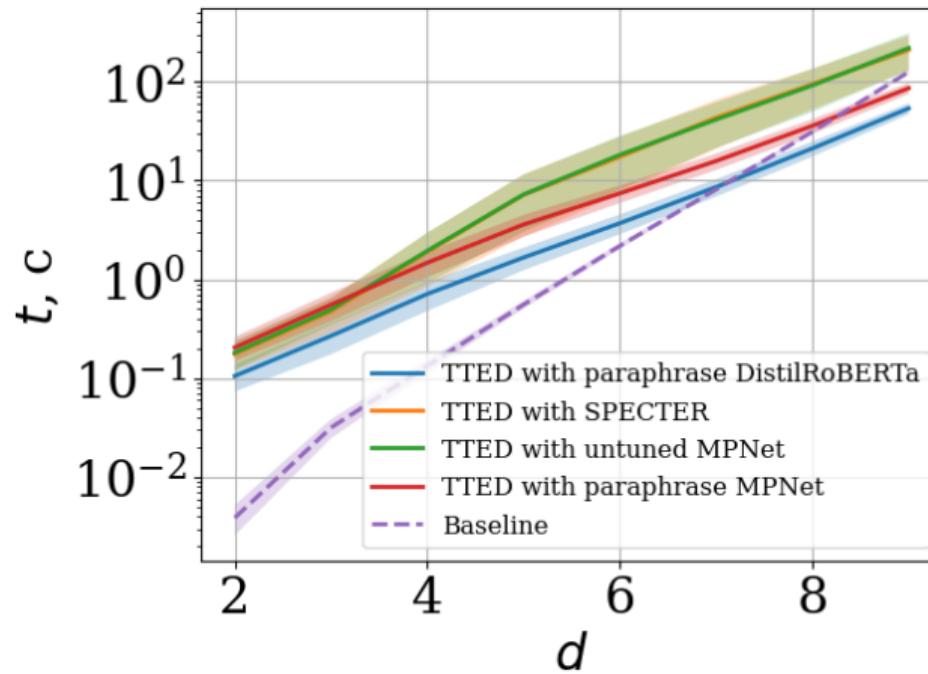

Dependence of quality coefficients on the use of **context** in TTED

Method	$R_S^D(\rho)$	$R_M^D(\rho)$
Without context	0.44 ± 0.12	0.48 ± 0.11
With context	0.43 ± 0.19	0.35 ± 0.08

The optimal and most interpretable TTED configuration is the one with the fine-tuned MPNet encoder, distance based on cosine similarity, and using texts from parent vertices as context.

Computation Time

Average computation times for different distances between full binary text trees of various depth d

Main Results

1. It has been shown that TTED reflects significant differences between text trees better than the previously used similarity coefficient.
2. An optimal configuration for TTED has been selected.
3. The proposed metric was implemented and can be used to assess quality in tasks like hierarchical summarization, mind map construction, and other tasks of automatic generation of text hierarchies.
